Function Context: C2

Function Background

This function comes from Airflow's connection-configuration module. Airflow can store connection information for databases, network services, and other external systems. The function encodes configuration information from a connection object into a URI string.

Input and Output

Input: The current connection object self, which stores the connection type, host, authentication information, port, path, and extra parameters.

Output: A URI string representing the connection information.

Side effect: The function may log a warning when the connection type contains discouraged characters.

Key Terms

Term	Meaning
URI	A string used to identify a connection resource.
connection type	The type of connection, such as a database or protocol type.
protocol	The protocol component of a URI.
host	The address of the target host.
port	The port of the connection target.
login	The login username.
password	The login password.
schema	The path component of a URI.
query parameter	An additional key-value pair following ? in a URI.
authority block	The URI component containing authentication information.
extra	Additional parameters in the connection configuration.

Helper Variables and Functions

Name	Brief Description
quote(...)	Escapes special characters in a URI.
urlencode(...)	Encodes key-value pairs as a query string.
parse_qsl(...)	Parses a query string into key-value pairs.
extra_dejson	Parses the extra configuration into a dictionary.
EXTRA_KEY	The wrapper-field name used when extra configuration cannot be expanded directly.
